

# Automated Reasoning

Luca Panariello

November 28, 2024

Automated Reasoning is the study of algorithms and systems that allow computers to reason about logical statements.

In this chapter, we will introduce the syntax and semantics of First-Order Logic (FOL), which is the most widely used logic in the field of Automated Reasoning.

We will also introduce the concept of a *model* and the notion of *validity* of a logical statement.

Automated Reasoning is achieved by using symbol reasoning, which is the manipulation of symbols according to the rules of logic.

# Chapter 1

## Propositional Logic

Propositional logic is a formal system that deals with propositions, which are statements that are either true or false.

### 1.1 Syntax of Propositional Logic

It is composed of a set  $\mathcal{V}$  of symbols called *propositional variables* which are denoted by  $P, Q, R, \dots$ ,  $x, y, z, \dots$ ,  $1, 2, 3, \dots$  or *true, false*.

An atomic variable are:

- $\top$  which is always true.
- $\perp$  which is always false.
- $P$  which is a propositional variable.

The logical connectives are  $\neg$  (negation),  $\wedge$  (conjunction),  $\vee$  (disjunction),  $\implies$  (implication) and  $\iff$  (equivalence).

#### Definition 1.1.1: Propositional Formula

A **propositional formula** is defined as follows:

- Every atomic variable is a formula.
- If  $F$  and  $G$  are formulas, then  $\neg F$ ,  $F \wedge G$ ,  $F \vee G$ ,  $F \implies G$ ,  $F \iff G$  are formulas.

### Definition 1.1.2: Propositional Interpretation

A **propositional interpretation** of a formula is a function that assigns a truth value to each atomic variable, and it is defined as follows:  $\mathcal{I} : \mathcal{V} \rightarrow \{true, false\}$ .

## 1.2 Semantic in Propositional Logic

An interpretation  $\mathcal{I}$  is said to *satisfy* a formula  $F$ , written as  $\mathcal{I} \models F$ :

- if  $F$  is an atomic variable  $P$ , then  $\mathcal{I}(P) = true$ .
- if  $F = \neg G$ , then  $\mathcal{I} \models F$  if  $\mathcal{I} \not\models G$ .
- if  $F = G \wedge H$ , then  $\mathcal{I} \models F$  if  $\mathcal{I} \models G$  and  $\mathcal{I} \models H$ .
- if  $F = G \vee H$ , then  $\mathcal{I} \models F$  if  $\mathcal{I} \models G$  or  $\mathcal{I} \models H$ .
- if  $F = G \implies H$ , then  $\mathcal{I} \models F$  if  $\mathcal{I} \not\models G$  or  $\mathcal{I} \models H$ .
- if  $F = G \iff H$ , then  $\mathcal{I} \models F$  if  $\mathcal{I} \models G$  and  $\mathcal{I} \models H$  or  $\mathcal{I} \not\models G$  and  $\mathcal{I} \not\models H$ .

### Definition 1.2.1: Satisfiable Formula

A formula  $F$  is **satisfiable** if  $\exists \mathcal{I}$  interpretation such that  $\mathcal{I} \models F$ .

### Definition 1.2.2: Valid Formula

A formula  $F$  is **valid** if  $\forall \mathcal{I}$  interpretation such that  $\mathcal{I} \models F$ .

### Remark 1.2.3: Unsatisfiable and Invalid Formulas

A formula  $F$  is **unsatisfiable** if  $\forall \mathcal{I}$  interpretation such that  $\mathcal{I} \not\models F$ . A formula  $F$  is **invalid** if  $\exists \mathcal{I}$  interpretation such that  $\mathcal{I} \not\models F$ .

### Remark 1.2.4: Implication of Validity

Let  $F$  be a formula, than we can observe that:

$F$		$\neg F$
Satisfiable	$\implies$	Invalid
Valid	$\implies$	Unsatisfiable
Invalid	$\implies$	Satisfiable
Unsatisfiable	$\implies$	Valid

[IDEA OF THE PROBLEM OF SATISFIABILITY IN PROPOSITIONAL LOGIC]  
[NOTE IN INTRODUZIONE 2 OTTOBRE]

Given a formula  $F$ , than  $F$  is finite, hence the number of propositional variables is finite, therefore the number of interpretations is finite.

In particular the number of interpretations is  $2^n$ , where  $n$  is the number of propositional variables.

[SCHEMA AD ALBERO] [INTRODUZIONE 2 OTTOBRE]

testing every interpretation is costly and inefficient, we need to design a decision procedure that is able to determine the satisfiability of a formula in a more efficient way, using normal forms.

[DECISION PROCEDURE] [INTRODUZIONE 2 OTTOBRE]

## 1.3 Normal Forms

### 1.3.1 Negation Normal Form

#### Definition 1.3.1: Negation Normal Form

A formula  $F$  is in **negation normal form** if the only connective that appears is  $\neg$ ,  $\wedge$ ,  $\vee$  and  $\neg$  is only applied to atomic variables.

The procedure to convert a formula  $F$  into negation normal form is as follows:

- $\neg\neg G \equiv G$ .
- $\neg(G \wedge H) \equiv \neg G \vee \neg H$ .
- $\neg(G \vee H) \equiv \neg G \wedge \neg H$ .
- $(G \implies H) \equiv \neg G \vee H$ .

- $(G \iff H) \equiv (\neg G \vee H) \wedge (G \vee \neg H)$

### 1.3.2 Disjunctive Normal Form

#### Definition 1.3.2: Disjunctive Normal Form

A formula  $F$  is in **disjunctive normal form** if it is a disjunction of conjunctions of atomic variables.

$$F = D_1 \vee D_2 \vee \dots \vee D_n \quad (1.1)$$

where  $D_i = (L_1^i \wedge L_2^i \wedge \dots \wedge L_n^i)$  is a conjunction of atomic variables called *cube*.

The procedure to convert a formula  $F$  into disjunctive normal form is to convert it into negation normal form and then apply the distributive law:

- $G \wedge (H \vee K) = (G \wedge H) \vee (G \wedge K)$ .
- $(G \vee H) \wedge K = (G \wedge K) \vee (H \wedge K)$ .

### 1.3.3 Conjunctive Normal Form

#### Definition 1.3.3: Conjunctive Normal Form

A formula  $F$  is in **conjunctive normal form** if it is a conjunction of disjunctions of atomic variables.

$$F = C_1 \wedge C_2 \wedge \dots \wedge C_n \quad (1.2)$$

where  $C_i = (L_1^i \vee \dots \vee L_n^i)$  is a disjunction of atomic variables called *clause*.

The procedure to convert a formula  $F$  into conjunctive normal form is to convert it into negation normal form and then apply the distributive law:

- $G \vee (H \wedge K) = (G \vee H) \wedge (G \vee K)$ .
- $(G \wedge H) \vee K = (G \vee K) \wedge (H \vee K)$ .

For the SAT problem, the conjunctive normal form is the most used normal form, because it is the most efficient to determine the satisfiability of a formula.

The distributive law cause the formula to grow exponentially, hence adding cost to the decision procedure.

# Chapter 2

## First-Order Logic

First Order Logic is a formal system that deals with logical statements that are more complex than propositional logic.

It is composed of a set of symbols that are used to represent logical statements, and a set of rules that define how these symbols can be combined to form logical statements.

It introduces the concept of *variables*, *functions* and *predicates*, which allows us to reason about objects and relations between objects.

### 2.1 Syntax in First-Order Logic

#### Definition 2.1.1: Signature

A **signature** is a tuple  $\Sigma = (\mathcal{C}, \mathcal{F}, \mathcal{P})$  where:

- $\mathcal{C}$  is a set of constant symbols.
- $\mathcal{F}$  is a set of function symbols.
- $\mathcal{P}$  is a set of predicate symbols.

The **constant** symbols denote individual elements (e.g. 0, 1,  $a$ ,  $b$ , ...).

The **function** symbols denote functions that take a number of arguments and return a value (e.g.  $+$ ,  $\times$ ,  $f$ ,  $g$ , ...).

The **predicate** symbols denote relations that take a number of arguments and return a truth value (e.g.  $=$ ,  $<$ ,  $P$ ,  $Q$ , ...).

The elements of  $\mathcal{C}$ ,  $\mathcal{F}$  and  $\mathcal{P}$  are called *symbols*.

The arity of a function or predicate symbol is the number of arguments it takes.

The difference between a function and a predicate lies in their connection, infact a function returns a value while a predicate returns a truth value.

#### Example 2.1.2: Predicate vs Function

$f(x) = f(y)$  these functions are connected by the equality predicate  $=$ , while these predicates  $P(x) \iff P(y)$  are connected by logical equivalence  $\iff$

#### Remark 2.1.3: Functions of Predicate

A predicate  $P$  can be seen as a function  $f_P$  that returns a truth value. So introducing a constant symbol  $\circ$  witch denotes “truth” than we can define  $f_P$  as:

$$f_P(x_1, \dots, x_n) = \circ \quad \text{if } P(x_1, \dots, x_n) \text{ is true}$$

where  $\circ$  is added to the signature.  $\Sigma' = \Sigma \cup \{\circ\}$

In FOL, there are logical connectives that are used to combine logical statements:  $\neg$  (negation),  $\wedge$  (conjunction),  $\vee$  (disjunction),  $\implies$  (implication),  $\iff$  (equivalence).

Using a signature  $\Sigma$  and a set of variables  $\mathcal{X}$ , we can define the syntax of FOL.

#### Definition 2.1.4: Term

Let  $\Sigma$  be a signature and  $\mathcal{X}$  a set of variables. A **term** is defined as follows:

- Every constant symbol  $c \in \mathcal{C}$  is a term.
- Every variable  $x \in \mathcal{X}$  is a term.
- Every  $n$ -ary function symbol  $f \in \mathcal{F}$  with  $t_1, \dots, t_n$  are terms, then  $f(t_1, \dots, t_n)$  is a term.

#### Definition 2.1.5: Atom

Let  $\Sigma$  be a signature and  $\mathcal{X}$  a set of variables. An **atom** is defined as follows:

- Every  $n$ -ary predicate symbol  $P \in \mathcal{P}$  with  $t_1, \dots, t_n$  are terms, then  $P(t_1, \dots, t_n)$  is an atom.

#### Definition 2.1.6: Literal

A **literal** is an atom or the negation of an atom.

### Definition 2.1.7: Formula

Let  $\Sigma$  be a signature and  $\mathcal{X}$  a set of variables. A **formula** is defined as follows:

- Every atom is a formula.
- If  $F$  and  $G$  are formulas, then  $\neg F$ ,  $F \wedge G$ ,  $F \vee G$ ,  $F \implies G$ ,  $F \iff G$  are formulas.
- If  $F$  is a formula and  $x \in \mathcal{X}$  is a variable, then  $\forall x.F$  and  $\exists x.F$  are formulas.

From a formula we can distinguish the *free variables* and the *bound variables*. The free variables are the variables that are not bounded by a quantifier, while the bound variables are.

### Example 2.1.8: Free and Bound Variables

Give the formula  $H$ :

$$f(x) = b \wedge \forall y.f(y) = b \implies f(f(y)) = b$$

We can define the free variables as  $FV(H) = \{x\}$  and the bound variables as  $BV(H) = \{y\}$ . While  $b$  is a constant symbol.

### Remark 2.1.9: Renaming Variables

Remark that a variable cannot be both free and bound at the same time. There is a issue with the renaming of variables: free variables cannot be renamed, while bound variables can, but the it cannot be renamed to a variable that is already in the formula.

[IMMAGINE VALIDITY PROBLEM IN FOL ][NOTE IN SIGNATURE 3 OTTO-BRE]

## 2.2 Semantics in First-Order Logic

### Definition 2.2.1: Interpretation

Let  $\Sigma$  be a signature. An **interpretation**  $\mathcal{I}$  of  $\Sigma$  is a tuple  $\mathcal{I} = (\mathcal{D}, \Phi)$  where:

- $\mathcal{D}$  is a non-empty set called the *domain* of  $\mathcal{I}$ .
- $\Phi$  is a function that assigns to each symbol in  $\Sigma$  an element of  $\mathcal{D}$ .

The function  $\Phi$  is defined as follows:

- $\forall c \in \mathcal{C}, \Phi(c) \in \mathcal{D}$ .
- $\forall f \in \mathcal{F}, \Phi(f) : \mathcal{D}^n \rightarrow \mathcal{D}$ .
- $\forall P \in \mathcal{P}, \Phi(P) : \mathcal{D}^n$ .

Where  $n$  is the arity of the function or predicate symbol.

So an interpretation assigns a meaning to the symbols in the signature, there can be multiple interpretations for the same signature.

### Example 2.2.2: Interpretation of Integers

Let  $\Sigma = (\{a, b\}, \{f\}, \{R\})$  be a signature. An interpretation  $\mathcal{I}$  of  $\Sigma$  can be defined as follows:

- $\mathcal{D} = \mathbb{Z}$ .
- $\Phi(a) = -3$ .
- $\Phi(b) = 3$ .
- $\Phi(f) = + : \mathbb{Z}^2 \rightarrow \mathbb{Z}$  is the addition function.
- $\Phi(R) = \geq : \mathbb{Z}^2$  is the greater than or equal to predicate.

### Example 2.2.3: Interpretation of Color

Let  $\Sigma = (\{a, b, c\}, \emptyset, \{R\})$  be a signature. An interpretation  $\mathcal{I}$  of  $\Sigma$  can be defined as follows:

- $\mathcal{D} = \{red, green, blue\}$ .
- $\Phi(a) = red$ .
- $\Phi(b) = blue$ .
- $\Phi(c) = green$ .
- $\Phi(R) = \{(red, blue), (red, red)\}$ .

A term  $t$  is evaluated in an interpretation  $\mathcal{I}$  as follows:

$$[t]_{\mathcal{I}} = \begin{cases} \Phi(c) & \text{if } t = c \in \mathcal{C} \text{ is a constant symbol} \\ \Phi(f)([t_1]_{\mathcal{I}}, \dots, [t_n]_{\mathcal{I}}) & \text{if } t = f(t_1, \dots, t_n) \in \mathcal{F} \text{ is a function symbol} \\ \beta(x) & \text{if } t = x \in \mathcal{X} \text{ is a variable} \end{cases}$$

Where  $n$  is the arity of the function symbol  $f$  and  $\beta$  is an assignment function that assigns a value to a variable.

## 2.3 Satisfaction and Validity in First-Order Logic

A formula  $F$  is evaluated in an interpretation  $\mathcal{I}$  and it is said to be *satisfied* in  $\mathcal{I}$  if it evaluates to true, noted as  $\mathcal{I} \models F$ , otherwise it is said to be *unsatisfied* in  $\mathcal{I}$ , noted as  $\mathcal{I} \not\models F$ .

The first-order formulas follows the same definition of satisfaction as the propositional formulas:

- **Satisfiable Formula** (1.2.1).
- **Valid Formula** (1.2.2).
- **Unsatisfiable Formula** (1.2.3).
- **Invalid Formulas** (1.2.3).
- **Implication of Validity** (1.2.4).

But the satisfiable relation for first-order formulas are defined as follows: Let  $F, G, H$  be formulas and  $\mathcal{I}$  be an interpretation, than:

- $\mathcal{I} \models \neg F$  if  $\mathcal{I} \not\models F$ .
- $\mathcal{I} \models F \wedge G$  if  $\mathcal{I} \models F \wedge \mathcal{I} \models G$ .
- $\mathcal{I} \models F \vee G$  if  $\mathcal{I} \models F \vee \mathcal{I} \models G$ .
- $\mathcal{I} \models F \implies G$  if  $\mathcal{I} \not\models F \implies \mathcal{I} \models G$ .
- $\mathcal{I} \models F \iff G$  if  $\mathcal{I} \models F \iff \mathcal{I} \models G$ .
- $\mathcal{I} \models \forall x.F$  if  $\forall d \in \mathcal{D} : \mathcal{I} \models_{\beta[x \rightarrow d]} G$
- $\mathcal{I} \models \exists x.F$  if  $\exists d \in \mathcal{D} : \mathcal{I} \models_{\beta[x \rightarrow d]} G$

Where  $\mathcal{I} \models_{\beta[x \rightarrow d]} G$  means that the formula  $G$  is satisfied in  $\mathcal{I}$  with the assignment function  $\beta$  that assigns the value  $d$  to the variable  $x$ .

$$\beta[x \rightarrow d](y) = \begin{cases} d & \text{if } y = x \\ \beta(y) & \text{otherwise} \end{cases} \quad \forall y \in \mathcal{X}$$

## 2.4 Logical Consequence

**Logical Consequence** is the relation between a set of formulas (assumptions) and a formula (conjecture), where the conjecture is true if the assumptions are true.

Let  $H$  be a set of formulas, called “*assumption*”, and  $\varphi$  be a formula, called “*conjecture*”:

We have that  $H \models \varphi$  or equivalently  $\models H \implies \varphi$ , which means that  $\varphi$  is **logical consequence** of  $H$ , then:

$$\forall \mathcal{I} \text{ interpretation} : \mathcal{I} \models H \iff \mathcal{I} \models \varphi \iff H \cup \{\neg \varphi\} \text{ is unsatisfiable}$$

The last coimplication derives from the fact that  $\neg \varphi$  is the negation of the conjecture, so if we find an interpretation that satisfies all the formulas in  $H$  then it must satisfy the conjecture, making the satisfaction of  $\neg \varphi$  impossible.

We need a way to determine if a formula is a logical consequence of a set of formulas: we can build a decision procedure that checks if the set of formulas is unsatisfiable, in particular the procedure checks if  $H \cup \{\neg \varphi\} \models \perp$ .

[IMMAGINE CON PROCEDURA IN 8 OTTOBRE]

# Chapter 3

## First-Order Theories

### 3.1 Theories in First-Order Logic

A **theory** formalize structures in a specific domain of interest, and help us reason about the properties of these structures. It really useful in verification.

Will be introduced some definitions that concerns theories in FOL.

#### Definition 3.1.1: Theory

A **theory**  $\mathcal{T}$  is defined as a tuple  $\mathcal{T} = (\Sigma, \mathcal{A})$  where:

- $\Sigma$  is a signature.
- $\mathcal{A}$  is a set of formulas called *axioms*, with only elements of the signature.

#### Definition 3.1.2: Sigma-Formula

A formula  $F$  is a  $\Sigma$ -**formula** if it contains symbols in the signature  $\Sigma$ , as well as the logical connectives, quantifiers and variables.

#### Definition 3.1.3: Theory-Interpretation

If  $\mathcal{I}$  is an interpretation of  $\Sigma$ , then  $\mathcal{I}$  is a  **$\mathcal{T}$ -interpretation** of a theory  $\mathcal{T} = (\Sigma, \mathcal{A})$  if  $\mathcal{I} \models \mathcal{A}$ .

### Definition 3.1.4: Theory-Satisfiable Formula

Let  $\mathcal{T} = (\Sigma, \mathcal{A})$  be a theory. And  $F$  be a  $\Sigma$ -formula. If  $\exists \mathcal{I}$  interpretation of  $\Sigma$ :

$$\mathcal{I} \models \mathcal{A} \wedge \mathcal{I} \models F$$

Which means that  $F$  is satisfied in  $\mathcal{I}$  and  $\mathcal{I}$  is a  $\mathcal{T}$ -interpretation.  
So  $F$  is  **$\mathcal{T}$ -satisfiable** in the theory  $\mathcal{T}$ .

### Definition 3.1.5: Theory-Valid Formula

Let  $\mathcal{T} = (\Sigma, \mathcal{A})$  be a theory. And  $F$  be a  $\Sigma$ -formula. If  $\forall \mathcal{I}$  interpretation of  $\Sigma$ :

$$\mathcal{I} \models \mathcal{A} \implies \mathcal{I} \models F$$

Which means  $F$  is valid ( $\models F$ ) in the theory  $\mathcal{T}$  if every  $\mathcal{T}$ -interpretation satisfies  $F$ .

Then  $F$  is a  **$\mathcal{T}$ -valid formula**, also noted as  $\mathcal{T} \models F$ .

### Definition 3.1.6: Theory Fragment

A **theory fragment** is a theory that deals only with a subset of formulas of the original theory.

### Definition 3.1.7: Quantifier-Free Fragment

The **quantifier-free fragment** of a theory  $\mathcal{T}$  is the theory that contains only the formulas that do not contain quantifier:  $\forall$  and  $\exists$ . Which means that the variables in the formulas are free.

## 3.2 Theory of Equality

The theory of equality is a theory that is centered around the **equality predicate**  $\simeq$  and the equivalence axioms.

### Definition 3.2.1: Equivalence Axioms

Let  $\mathcal{X}$  be a set of variables and  $\simeq$  be a predicate symbol. Let  $\mathcal{A}$  be a set of formulas called **equivalence axioms** if it contains the following formulas:

- **Reflexivity:**  $\forall x \in \mathcal{X}. \quad x \simeq x.$
- **Symmetry:**  $\forall x, y \in \mathcal{X}. \quad x \simeq y \implies y \simeq x.$
- **Transitivity:**  $\forall x, y, z \in \mathcal{X}. \quad x \simeq y \wedge y \simeq z \implies x \simeq z.$

### Definition 3.2.2: Congruence Axioms

Let  $\mathcal{X}$  be a set of variables and  $\simeq$  be a predicate symbol. Let  $\mathcal{F}$  be a set of function symbols and  $\mathcal{P}$  be a set of predicate symbols. Let  $\mathcal{A}$  be a set of formulas called **congruence axioms** if it contains the following formulas:

- **Function Congruence:**  $\forall$  function symbol  $f \in \mathcal{F}$  with arity  $n$  and  $\forall x_1, \dots, x_n, y_1, \dots, y_n \in \mathcal{X}$ :

$$x_1 \simeq y_1 \wedge \dots \wedge x_n \simeq y_n \implies f(x_1, \dots, x_n) \simeq f(y_1, \dots, y_n)$$

- **Predicate Congruence:**  $\forall$  predicate symbol  $R \in \mathcal{P}$  with arity  $n$  and  $\forall x_1, \dots, x_n, y_1, \dots, y_n \in \mathcal{X}$ :

$$x_1 \simeq y_1 \wedge \dots \wedge x_n \simeq y_n \implies R(x_1, \dots, x_n) \iff R(y_1, \dots, y_n)$$

Which states that if the arguments of a function or predicate are equal, then the result of the function or the truth value of the predicate is equal.

### Definition 3.2.3: Theory of Equality

Let  $\Sigma_E = (\mathcal{C}, \mathcal{F}, \mathcal{P} \cup \{\simeq\})$  be a signature. Let  $\mathcal{A}_E$  be a set of formulas called **equality axioms** if it contains the Equivalence Axioms and the Congruence Axioms. The it can be defined the **theory of equality** as:

$$\mathcal{T}_E = (\Sigma_E, \mathcal{A}_E)$$

#### Notation 3.2.4: Disequality in Theory of Equality

It is possible to define the **disequality predicate**  $\neq$  as:

$$x \neq y \iff \neg(x \simeq y)$$

Where  $x$  and  $y$  are variables in  $\mathcal{X}$ . It is also possible to redefine the equality signature as:

$$\Sigma_E = (\mathcal{C}, \mathcal{F}, \mathcal{P} \cup \{\simeq, \neq\})$$

#### Remark 3.2.5: Theory of Equality

Since the equality axioms contain the equivalence axioms and the congruence axioms, then the equality predicate  $\simeq$  is a **congruence relation**.

#### Example 3.2.6: Satisfiability in Theory of Equality

The formula  $a \simeq b \wedge f(a) \simeq f(b)$  is satisfiable in the theory of equality ( $\mathcal{T}_E$ -satisfiable). While the formula  $a \simeq b \wedge R(a) \iff \neg R(b)$  is unsatisfiable in the theory of equality ( $\mathcal{T}_E$ -unsatisfiable).

#### Notation 3.2.7: Nested Function

The notation  $f^{(n)}(x)$  denotes the  $n$ -th iteration of the function  $f$  on the argument  $x$ :

$$f^{(n)}(x) = \underbrace{f(f(\dots f(x) \dots))}_n$$

### Example 3.2.8: Human Reasoning for Satisfiability

Let the formula:

$$F = \underbrace{f^{(3)}(x) \simeq x}_{\text{EQ1}} \wedge \underbrace{f^{(5)}(x) \simeq x}_{\text{EQ2}} \wedge \underbrace{f(x) \not\simeq x}_{\text{EQ3}}$$

Using human reasoning we can see that:

- $\text{EQ1} + \text{EQ2} \implies f^{(2)}(x) \simeq x$  (EQ4).
- $\text{EQ1} + \text{EQ4} \implies f(x) \simeq x$  (EQ5).
- $\text{EQ3} + \text{EQ5} \implies \perp$ .

So the formula  $F$  is unsatisfiable.

The human reasoning is not efficient for large formulas, and for machines, we need a decision procedure that can determine the satisfiability with an algorithm that can be executed by a computer.

# Chapter 4

## QF-Fragment of the Theory of Equality

Non all the Logic formulas can be decided by a decision procedure:

- **PL** (Propositional Logic) is decidable problem.
- **Fragment of FOL** is decidable problem.
- **FOL** (First-Order Logic) formula is valid is a semi-decidable problem.
- **FOL** formula is invalid is a non-semi-decidable problem.
- **HOL** (Higher-Order Logic) is undecidable problem.

In this paper we will focus on the **PL** and **FOL** formulas.

In particular we will focus on the **QF-Fragment of the Theory of Equality** (QF- $\mathcal{T}_E$ ).

### 4.1 Formulas in QF-Fragment of the TOE

The QF- $\mathcal{T}_E$  is the fragment of the first-order logic that contains only quantifier-free formulas and the equality predicate.

The idea is to restrict the formulas to a certain form in order to make the problem decidable by the same decision procedure.

This “*preprocessing*” can be done with the following steps:

1. Remove all the quantifiers.

2. Transform the formula in NNF (1.3.1).
3. Transform the formula in DNF (1.3.2).
4. Removing all other predicate symbols except the equality predicate (2.1.3)

In this way the formula is in the  $\text{QF-}\mathcal{T}_E$ , and it can be expressed as a conjunction of equalities and disequalities.

In this way if a block of the formula is false, the whole formula is unsatisfiable.

The  $\text{QF-}\mathcal{T}_E$ -Formula  $F$  can also be expressed as a set of equations and disequations:

$$F = \{s_i \simeq t_i\}_{i=1}^n \cup \{s_j \not\simeq t_j\}_{j=n+1}^{n+m}$$

Where  $s_i, t_i, s_j, t_j$  are terms.

## 4.2 Congruence Closure of a Binary Relation

### Definition 4.2.1: Binary Relation

A **binary relation**  $R$  is a subset of the cartesian product of a set  $S$  and itself.

$$R \subseteq S \times S$$

### Definition 4.2.2: Equivalence Relation

A binary relation  $R$  is an **equivalence relation** if it satisfies the *equivalence axioms* 3.2.1 for the predicate.

### Definition 4.2.3: Congruence Relation

A equivalence relation  $R$  is a **congruence relation** if it satisfies the *congruence axioms* 3.2.2 for the predicate.

### Definition 4.2.4: Equivalence Class

Given a set  $S$  and an equivalence relation  $R$  on  $S$ , the **equivalence class** of an element  $s \in S$  is the set:

$$[s]_R = \{t \in S \mid sRt\}$$

#### Example 4.2.5: Modulo 2 Equivalence Class

Given the set  $S = \mathbb{Z}$  and the equivalence relation  $R$  defined as:

$$sRt \iff s \equiv t \pmod{2} \iff s \equiv_2 t$$

The equivalence class of 0 is:

$$[0]_{\equiv_2} = \{\dots, -4, -2, 0, 2, 4, \dots\}$$

#### Definition 4.2.6: Refinement

Let  $R$  and  $R'$  be two equivalence relations on a set  $S$ . The relation  $R$  is a **refinement** of  $R'$  if:

$$\forall s, t \in S \ sRt \implies sR't$$

Which means  $R \subsetneq R'$ , and it is denoted as  $R \sqsubseteq R'$ .

#### Remark 4.2.7: Refinement

We can say that the relation  $R$  is a refinement of the relation  $R'$ . But  $R'$  is not a refinement of  $R$ , in fact:

$$\forall s, t \in S \ sR't \not\Rightarrow sRt$$

#### Example 4.2.8: Refinement of Modulo 2 Class

We can say that the relation  $\equiv_4$  is a refinement of the relation  $\equiv_2$ .

$$\forall s, t \in \mathbb{Z} \ s \equiv_4 t \implies s \equiv_2 t$$

[IMAGE OG CLASS EQUIVALENCE IN 8 OTTOBRE]

#### Definition 4.2.9: Partition

A **partition** of a set  $S$  is a set of non-empty subsets of  $S$ :

$$\{S_1, S_2, \dots, S_n\}$$

such that every element of  $S$  is in exactly one of these subsets:

- $S_i \neq \emptyset$
- $S_i \cap S_j = \emptyset \quad \forall i \neq j$
- $\bigcup_{i=1}^n S_i = S$

#### Definition 4.2.10: Equivalence Closure

Let  $R$  be a binary relation on a set  $S$ . The **equivalence closure**  $R^E$  of  $R$  such that:

- $R^E$  is an equivalence relation
- $R^E$  covers  $R$ ,  $R \subseteq R^E$
- $R^E$  is the  $\subseteq$ -smallest equivalence relation s.t.  $R \subseteq R^E$ , in other words if  $\exists R' : R \subseteq R'$  and  $R'$  is an equivalence relation, then  $R^E \subseteq R'$ .

#### Definition 4.2.11: Congruence Closure

Let  $R$  be a binary relation on a set  $S$ . The **congruence closure**  $R^C$  of  $R$  such that:

- $R^C$  is a congruence relation
- $R^C$  covers  $R$ ,  $R \subseteq R^C$
- $R^C$  is the  $\subseteq$ -smallest congruence relation s.t.  $R \subseteq R^C$ , in other words if  $\exists R' : R \subseteq R'$  and  $R'$  is a congruence relation, then  $R^C \subseteq R'$ .

The idea is to use the congruence closure to check if a set of equalities and disequalities are satisfiable ( $R = \simeq$ ).

If the congruence closure of the set is the equality relation put an equality relation and a disequality relation in the same equivalence class, then the formula is unsatisfiable.

## 4.3 Congruence Closure Algorithm

The **Congruence Closure Algorithm** is an algorithm that computes the congruence closure of a binary relation, and it is used to check the satisfiability of a set of equalities and disequalities.

### 4.3.1 Idea of the CCA

Let a set of equalities and disequalities  $F$ :

$$F = \underbrace{\{s_i \simeq t_i\}_{i=1}^n}_{F^+} \cup \underbrace{\{s_j \not\simeq t_j\}_{j=n+1}^{n+m}}_{F^-}$$

we want to check if  $F$  is satisfiable.

We construct the set of all terms of  $F$ :

$$S_F = \{s_i \mid i = 1, \dots, n+m\} \cup \{t_i \mid i = 1, \dots, n+m\}$$

We need to find an interpretation  $\mathcal{I}$  that satisfies  $F$  such that:

- $\mathcal{I} = (S_F, \Phi)$
- $\Phi(\simeq) = \sim \subseteq S_F \times S_F$  congruence relation over the terms classes
- $\begin{cases} \mathcal{I} \models s_i \simeq t_i \\ \mathcal{I} \not\models s_j \simeq t_j \end{cases} \iff \begin{cases} [s_i]_{\mathcal{I}} \sim [t_i]_{\mathcal{I}} & \forall i = 1, \dots, n \\ [s_j]_{\mathcal{I}} \not\sim [t_j]_{\mathcal{I}} & \forall j = n+1, \dots, n+m \end{cases}$

So we can follow the following steps:

1. Construct the set of terms  $S_F$ .
2. Construct the initial congruence relation using the equalities in  $F^+$  forming a sort of partition  $P_F$ .
3. Continue to refine  $P_F$  using the equalities in  $F^+$ .
4. If a equality in  $P_F$  is found in  $F^-$ , then the formula is unsatisfiable.
5. If all the equalities in  $F^+$  are in  $P_F$ , so that the set has only one congruence class, then the formula is satisfiable.

### Example 4.3.1: Congruence Closure Algorithm - SAT

Let  $F = \{x \simeq y \wedge f(x) \simeq f(z)\}$  and compute the congruence closure algorithm of  $F$ .

$$S_F = \{x, y, f(x), f(z)\}$$

We start with the initial partition:

$$P_F = \{\{x, y\}, \{f(x), f(z)\}\}$$

For the congruence axioms 3.2.2 we have:

$$x \simeq y \implies f(x) \simeq f(y)$$

So we refine the partition:

$$P_F = \{\{x, y, f(x), f(y)\}\}$$

$P_F$  has only one equivalence class, so the formula is satisfiable.

### Example 4.3.2: Congruence Closure Algorithm - UNSAT

Let  $F = \underbrace{f^{(5)} \simeq x}_{EQ1} \wedge \underbrace{f^{(3)} \simeq x}_{EQ2} \wedge \underbrace{f(x) \not\simeq x}_{DEQ}$ .

$$S_F = \{f^{(5)}(x), f^{(4)}(x), f^{(3)}(x), f^{(2)}(x), f(x), x\}$$

The initial partition is:

$$P_F = \{\{f^{(5)}(x)\}, \{f^{(4)}(x)\}, \{f^{(3)}(x)\}, \{f^{(2)}(x)\}, \{f(x)\}, \{x\}\}$$

We refine the partition with the equalities:

$$\begin{aligned} P_F &\stackrel{EQ1}{=} \{\{f^{(5)}(x), x\}, \{f^{(4)}(x)\}, \{f^{(3)}(x)\}, \{f^{(2)}(x)\}, \{f(x)\}, \{x\}\} \\ &\stackrel{EQ2}{=} \{\{f^{(5)}(x), f^{(3)}(x), x\}, \{f^{(4)}(x)\}, \{f^{(2)}(x)\}, \{f(x)\}, \{x\}\} \\ &\stackrel{EQ1 \wedge EQ2}{=} \{\{f^{(5)}(x), f^{(3)}(x), f^{(2)}(x), x\}, \{f^{(4)}(x)\}, \{f(x)\}, \{x\}\} \\ &\stackrel{f^{(2)}(x) \simeq x \wedge f(x) \not\simeq x}{=} \{\{f^{(5)}(x), f^{(3)}(x), f^{(2)}(x), f(x), x\}, \{f^{(4)}(x)\}\} \end{aligned}$$

Since the disequality  $f(x) \not\simeq x$  is in the partition, the formula is unsatisfiable.

### 4.3.2 Algorithm of CCA

We can express the congruence classes as a Directed Acyclic Graph (DAG) where the nodes are the terms and the edges are the equalities.

[IMAGE OF DAG FROM 15 OTTOBRE]

We can define the data structure of the nodes of the DAG as:

Code 4.3.3: Node Structure

```
1 public class Node {
2     /**
3      * The unique identifier of the function or
4      * variable.
5      * A constant integer.
6      */
7     public final Integer id;
8
9     /**
10     * The name of the function or variable.
11     * A constant string.
12     */
13     public final String name;
14
15     /**
16     * The list of arguments associated with the
17     * function.
18     * Empty for variables.
19     * An ordered constant ArrayList.
20     */
21     private final Integer[] args;
22
23     /**
24     * The representative id of the function or
25     * variable.
26     * A mutable integer
27     */
28     public Integer find;
29
30     /**
31     * The set of congruence closure parent (ccpar).
32     * An unordered mutable set of integers.
33     */
34     public Set<Integer> ccpar;
35 }
```

The Node data structure will represent a singular term.

Then we can define some basic functions:

#### Code 4.3.4: Node Function

```
1 Node NODE(Integer id){
2     return nodes.get(id);
3 }
    ;
```

#### Code 4.3.5: Find Function

```
1 Integer FIND(Integer id){
2     Node N = NODE(id);
3     if (N.find == id){
4         return id;
5     } else {
6         return FIND(N.id);
7     }
8 }
    ;
```

#### Code 4.3.6: Ccpar Function

```
1 Set<Integer> CCPAR(Integer id){
2     return NODE(FIND(id)).ccpar;
3 }
    ;
```

These functions will retrieve the respective object.

We then define the Union Function which will unite two nodes in a single congruence class:

#### Code 4.3.7: Union Function

```
1 void UNION(Integer id1, Integer id2){
2     Node N1 = NODE(FIND(id1));
3     Node N2 = NODE(FIND(id2));
4     N1.find = N2.find;
5     N2.ccpair.addAll(N1.ccpair);
6     N1.ccpair = Collections.emptySet();
7 }
    ;
```

But before the union, we need to check if the terms are congruent with each other, we define a function to do so:

#### Code 4.3.8: Congruent Function

```
1 Boolean congruenceCheck(Node N1, Node N2){
2     if (N1.name != N2.name | N1.arity != N2.arity){
3         return false;
4     }
5     if (Arrays.equals(N1.args(), N2.args())){
6         return true;
7     } else {
8         return false;
9     }
10 }
11
12 Boolean CONGRUENT(Integer id1, Integer id2){
13     Node N1 = NODE(id1);
14     Node N2 = NODE(id2);
15     return congruenceCheck(N1, N2);
16 }
    ;
```

We in the end define a function that procede to check if two terms of a class are congruent and union them if so, also, ccpair and rrepresentative (find), are modified to respect these invariants for a **Rrepresentative Node**:

- `n.id == n.fint`
- `n.ccpair =  $\emptyset$`

### Code 4.3.9: Merge Function

```
1 void MERGE(Integer id1, Integer id2){
2     if (FIND(id1) != FIND(id2)) {
3         Set<Integer> P1 = CCPAR(id1);
4         Set<Integer> P2 = CCPAR(id2);
5         UNION(id1, id2);
6         for (Integer t1 : P1) {
7             for (Integer t2 : P2) {
8                 if (FIND(t1) != FIND(t2) & CONGRUENT(
9                     id1, id2)){
10                     MERGE(t1, t2);
11                 }
12             }
13         }
14     }
15 }
```

### 4.3.3 Complexity of CCA

Let  $n$  be the number of nodes and  $e$  the number of edges in the initial DAG.

The complexity of the CCA is  $O(e^2)$  for  $O(n)$  calls of the merge function. Some optimizations can be done to reduce the complexity to  $O(e \log e)$  for  $O(n)$  calls of the merge function.

### 4.3.4 Optimization of CCA

We can build a non recursive version of the FIND function:

#### Code 4.3.10: Iterative Fine Function

```
1 import java.util.Collections;
2
3 Integer ITER_FIND(Integer id){
4     Node N = NODE(id);
5     return N.find
6 }
7
8 void UNION(Integer id1, Integer id2){
9     Node N1 = NODE(FIND(id1));
10    Node N2 = NODE(FIND(id2));
11    for (Node N : nodes.values()) {
12        if (N.find == N1.find){
13            N.find = N2.find;
14        }
15    }
16    N1.find = N2.find;
17    N2.ccpair.addAll(N1.ccpair);
18    N1.ccpair = Collections.emptySet();
19 }
;
```

This function will find the representative of a node in a non recursive way, with the assumption that all the nodes of the non representative nodes have the representative node as the chosen node for the congruence class, during the union operation.

We can also apply an heuristic to reduce the number of node to unite in the union operation, by choosing the node with the largest ccpair set as the representative node:

### Code 4.3.11: Union Function with Euristic

```
1 public void EUR_UNION(int id1, int id2){
2     Node N1 = NODE(FIND(id1));
3     Node N2 = NODE(FIND(id2));
4     Node R;
5     Node N;
6     if (N1.ccpar.size() > N2.ccpar.size()){
7         R = N1;
8         N = N2;
9     } else {
10        R = N2;
11        N = N1;
12    }
13    for (Node M : nodes.values()) {
14        if (M.find == N.find){
15            M.find = R.find;
16        }
17    }
18    N.find = R.find;
19    R.ccpar.addAll(N1.ccpar);
20    N.ccpar.clear();
21 }
```

;

In the end we can add a forbidden set to the node structure, to check forbidden merges (contradictions), and avoid them:

#### Code 4.3.12: Forbidden Set Euristic

```
1 private boolean FORBIDDEN(int id1, int id2){
2     Node N1 = NODE(id1);
3     Node N2 = NODE(id2);
4     if (N1.forb.contains(N2.find) || N2.forb.contains
5         (N1.find)){
6         this.unsatFlag = true;
7         return true;
8     }
9     return false;
10 }
11
12 public void UNION(int id1, int id2){
13     Node N1 = NODE(FIND(id1));
14     Node N2 = NODE(FIND(id2));
15     Node R;
16     Node N;
17     if (N1.ccpar.size() > N2.ccpar.size()){
18         R = N1;
19         N = N2;
20     } else {
21         R = N2;
22         N = N1;
23     }
24     N.find = R.find;
25     R.ccpar.addAll(N1.ccpar);
26     N.ccpar.clear();
27     R.forb.addAll(N.forb);
28     N.forb.clear();
29 }
```

In this case we can check if the merge is forbidden, and if so interrupt the entire algorithm using the `unsatFlag`.
